

FIBROUS NONWOVEN WEBS

Abstract of the Invention

5 New fibrous nonwoven webs are taught that comprise a mass of
polyethylene terephthalate fibers that exhibit a double melting peak on a DSC plot:
one peak is representative of a first molecular portion within the fiber that is in
non-chain-extended crystalline form, and the other peak is representative of a
second molecular portion within the fiber that is in chain-extended crystalline form
and has a melting point elevated over that of the non-chain-extended crystalline
10 form. Webs comprising fibers having such a morphology have a unique
combination of durability and dimensional stability. The fibers are generally
autogenously bonded at points of fiber intersection.
